

# USACO Bronze Basic A - 9. Strings

## 1. Strings

- The class provided by the C++ STL, literally a class that handles strings.
- In C, strings are handled in the form of `char[]`, but in C++, strings are used as a type of variable, making it much more versatile and easier to handle strings.
- Unlike `char[]`, the `'\0'` character is not inserted at the end of the string, and the length of the string can be changed dynamically.

## 2. I/O of Strings

- Input/output is possible with the C++ input/output method, `cin` and `cout`, and the `getline` function can also be used, so we need to include header file name `iostream`
- `scanf` and `printf` in C cannot be used.

`string str; // create string`

`cin >> str; // Receives the string before the space.`

`getline(cin, str); // The string up to '\n', that is, the entire line is input. (with spaces)`

`getline(cin, str, 'a') // Gets the string up to 'a' character.`

`getline(cin, str, '\n') //== getline(cin, str)`

`cout << str; // print a string`

```
string str;
getline(cin, str);
cout << "str : " << str << '\n';
getline(cin, str, 'd');
cout << "str : " << str << '\n';
cin >> str;
cout << "str : " << str << '\n';
```

### 3. Initialize Strings

- We have to include header file name string like `#include<string>`

<code>string str;</code>
<code>string str = "abcdef";</code>
<code>string str;</code> <code>str = "abcdef";</code>
<code>string str("abcdef");</code>
<code>string str2(str1);</code>

### 4. Operation for Strings

- Operators such as `<`, `>`, `==`, and `+` can be used with the string class.
- String comparison (`<`, `>`, `==`): You can compare the dictionary order of two strings or check whether they are identical.
- String concatenation (`+`): Connects two strings.

### 5. Member functions for Strings

<code>str.at(index)</code>
<code>str[index]</code>
<code>str.front()</code>
<code>str.back()</code>

<code>str.size()</code>
<code>str.capacity()</code>
<code>str.resize(n)</code>
<code>str.resize(n, 'a')</code>
<code>str.shrink_to_fit()</code>
<code>str.reserve(n)</code>
<code>str.empty()</code>

<code>str.append(str2)</code>
<code>str.append(str2, n, m)</code>
<code>str.append(n, 'a')</code>
<code>str.insert(n, str2)</code>
<code>str.replace(n, k, str2)</code>
<code>str.clear()</code>
<code>str.erase(n, m)</code>
<code>str.erase(n, m) (iterator)</code>
<code>str.erase()</code>
<code>str.push_back(c)</code>
<code>str.pop_back()</code>
<code>str.assign(str2)</code>

<code>str.find("abcd")</code>
<code>str.find("abcd", n)</code>
<code>str.substr()</code>
<code>str.substr(n)</code>
<code>str.substr(n, k)</code>
<code>str.compare(str2)</code>
<code>swap(str1, str2)</code>
